# General Considerations, part 1 of 2

It was written a stand-alone program in order to:

- given a differential cross section generates  $\cos\theta$  and  $\phi$  according to the proper distribution.
- computes the 4-momenta of the products (knowing the masses and the CM energy) in the most useful frame and takes them back in the LAB frame, provided that each decay is a 2-body one.
- computes the distribution for the flight length (knowing the mean lifetime,LAB frame) and the 3 momenta module (frame has to be chosen) of each particle

The electron has an energy  $E_e >> m_e$  and so it has the positron, in this condition:

$$E_p \sim \frac{s}{4E_e} \quad \beta_{cm} \sim \frac{E_e - E_p}{E_e + E_p} \qquad \gamma_{cm} = \frac{1}{\sqrt{1 - \beta_{cm}^2}} \tag{1}$$

Where s is the Mandelstam variable,  $\beta_c m$  is the center of mass speed. The differential cross section in the C.M. (center of mass) frame for the process can be factorized as:

$$d\sigma(e^{+} + e^{-} \longrightarrow f + \bar{f}) = f(\cos(\theta))g(\phi) \ d\phi d\cos(\theta)$$

# General Considerations, part 2 of 2

Expression for a generic Lorentz's Boost in the  $\vec{v}$  direction.

$$B(\vec{v}) = \begin{bmatrix} \gamma & -\gamma v_{x}/c & -\gamma v_{y}/c & -\gamma v_{z}/c \\ -\gamma v_{x}/c & 1 + (\gamma - 1)\frac{v_{x}^{2}}{v^{2}} & (\gamma - 1)\frac{v_{x}v_{y}}{v^{2}} & (\gamma - 1)\frac{v_{x}v_{z}}{v^{2}} \\ -\gamma v_{y}/c & (\gamma - 1)\frac{v_{y}v_{x}}{v^{2}} & 1 + (\gamma - 1)\frac{v_{y}^{2}}{v^{2}} & (\gamma - 1)\frac{v_{y}v_{z}}{v^{2}} \\ -\gamma v_{z}/c & (\gamma - 1)\frac{v_{z}v_{x}}{v^{2}} & (\gamma - 1)\frac{v_{z}v_{y}}{v^{2}} & 1 + (\gamma - 1)\frac{v_{z}}{v^{2}} \end{bmatrix}$$

The mean flight length is:

$$< I >= \gamma \tau c \beta$$

Where  $\gamma = \frac{1}{\sqrt{1-\beta^2}}$ ,  $\beta$  is the speed of the particle in the LAB frame,  $\tau$  is the particle mean lifetime, a particle decays in a length distributed as:

$$f(L) = \frac{1}{\langle I \rangle} e^{-\frac{L}{\langle I \rangle}} \tag{4}$$

Thesis

## Example, part 1 of 3

It has been studied the decay  $\tau \to \Lambda^0 + \pi$  in PEP-II asymmetric collider  $e^+e^-$  which  $e^-$ 's beam energy is 9.0 GeV and the center of mass energy is the  $\Upsilon(4S)$  level: 10.56 GeV. Other useful datas are:

- the  $\pi$ 's mass: 0.139 GeV;
- the  $\tau$ 's mass: 1.77 GeV;
- the Λ<sup>0</sup>'s mass: 1.11 GeV.

Here the values in equation (1) for the case studied:

$$E_{pos} = 3.09 \; \text{GeV} \quad \beta_{cm} = 0.487 \quad \gamma_{cm} = 1.14$$

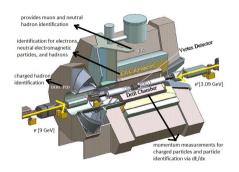

Figure: BaBar detector scheme.

### Example, part 2 of 3

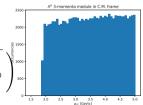

The differential cross section for the process  $e^+ + e^- \rightarrow \tau^+ + \tau^-$  in the C.M. frame is:

$$\frac{d\sigma}{d\Omega} = N_c \frac{\alpha^2}{4s} \beta [1 + \cos^2(\theta) + (1 - \beta^2) \sin^2(\theta) \ Q_f^2 \ (5)$$

Where s is the Mandelstam variable,  $\beta$  is v/c for the produced fermions in the c.m.,  $\theta$  is the c.m scattering angle,  $Q_f$  is the charge of the lepton and  $N_c$  is 1 for charged leptons and 3 for quarks.

 $\Lambda^0$ 's 3-momenta kinematics lower limit is 1.8 GeV/c in the c.m., here is 4-momenta in frame at rest with respect the  $\tau$ :

Thesis March 19, 2021

#### Example, part 3 of 3

The flight length of the  $\Lambda^0$  is required to be  $L_{\Lambda^0} > 1$  cm so the efficiency is about 97%. Within a sphere of radius 0.2 cm from the collisions center there are all the  $\tau$ 's decay.
